What is Diabetes?

(Metabolically?....)

Elevated fasting sugar > 126 mg/dl
(or 2hr post prandial sugar > 200 mg/dl)

Insufficient insulin to suppress gluconeogenesis

Variable levels of *insulin resistance* in the liver and periphery (muscle and fat)

Pathophysiology of Glycemic Microvasculopathy-1

- **Hemoglobin A1c (HbA1c) is the sugarization or "*Stickiness-index*" which measures the percentage of hemoglobin - a protein, sitting innocently within the membrane-protected environment of the red blood cell, whose function it is to bind O2 in the lungs and release it in the tissues - which is covalently stuck to glucose (*maple syrup*)**

- **Correlates virtually linearly with the level and duration (*average*) of glucose concentration over the preceding three months or so:-**

•60 mg/dl <=> 4%	90 mg/dl <=> 5%
•120 mg/dl<=> 6%	150 mg/dl<=> 7%
•180 mg/dl<=> 8%	210 mg/dl<=> 9%
•240 mg/dl<=> 10%	270 mg/dl<=> 11%
•300 mg/dl<=> 12%	330 mg/dl<=> 13%
•360 mg/dl<=> 14%	390 mg/dl<=> 15%

pharmanet

Pathophysiology of Glycemic Microvasculopathy-2

- **Correlates with the pathophysiologic glycosylation of (*glucose-stickiness to*) proteins in the vasculature**
- **Correlates with small-vessel complications as glycosylated proteins cause more obstruction to red-cell flow in smaller caliber arteries than in larger caliber arteries**

- **Target is an A1c of 7% Hemogobin sugarization with action suggested if the Hemoglobin sugarization exceeds 8%**
- **Correlates with the life span of the red cell and is therefore dependent on a normal (3 month or so) red-cell survival**

NIDDK/NHLBI/NDC/AHA/ADA Statement

NHLBI/NIDDK/AHA/ADA/NDC Statement (1 Sep 1999)

Diabetes Mellitus: A Major Risk Factor for Cardiovascular Disease

Statement from Dr. Claude Lenfant, Director, National Heart, Lung, and Blood Institute, and Dr. Phillip Gorden, Director, National Institute of Diabetes and Digestive and Kidney Diseases, National Institutes of Health

The National Heart, Lung, and Blood Institute (NHLBI) and National Institute of Diabetes and Digestive and Kidney Diseases (NIDDK) of the National Institutes Diseases (NIDDK) of the National Instiutes Health (NIH) have collaborated with three leading private health organizations on a major public health statement to alert physicians, patients, and the general public

to the increasing significance of diabetes mellitus as a major risk factor for cardiovascular disease.

In joining this effort, each organization reaffirms its commitment to better understand the causes and unique factors that contribute to excess risk of premature CVD in persons with diabetes, and to develop and implement improved treatments to reduce these complications.

UMDS

Dr. Harry Keen (1968)[2]

"It is, of course, possible to formulate three standard hypotheses to explain the relationship - that A causes B, that B causes A, or that both A and B are caused by C. We have chosen to examine what is perhaps the most likely and potentially the most useful of these explanations - that hyperglycemia contributes causally to the development of the arterial lesions. It is a useful explanation because there is long experience and knowledge of methods aimed at lowering the blood sugar: the possibility of intervening in the progress of a disease process is one which stimulates both the interest of the doctor and the co-operation of the patient." (Keen H, Jarrett, RJ, Chlouverakis C, Boyns DR, The effect of treatment of moderate hyperglycemia on the incidence of arterial disease. *Postgrad. Med.J*. [1968] **44**:960)

pharmanet

3a) If not, can *markers* which may precede diabetes but are not necessarily associated with poor control also be shown to associate with increased cardiovascular mortality?

pharmanet

Cytokines….[3a]

There is some newly emerging data that atherosclerosis, type 2 diabetes, and obesity are all characterized by increased plasma or serum levels of inflammatory vasoactive cytokines. M. Visser and colleagues (*JAMA*[1999] 282:2131-2135) have reported that, "*Higher BMI is associated with higher CRP concentrations, even among young adults aged 17 to 39 years. These findings suggest a state of low-grade systemic inflammation in overweight and obese persons*." Hak et al reported in1999 (*Arteriosclerosis, Thrombosis, and Vascular Biology* **19**:1986-1991) that C-Reactive Protein associates with measures of obesity, insulin resistance, and subclinical atherosclerosis in healthy, middle-aged women. Also, John Yudkin's group has data recently published (*Arteriosclerosis, Thrombosis, and Vascular Biology* (1999) 19: 972-978) that "adipose tissue is an important determinant of a low level, chronic inflammatory state as reflected by levels of interleukin-6, tumor necrosis factor-, and C-reactive protein, and that infection with H pylori, C pneumoniae, and cytomegalovirus is not …[and] support the concept that such a low-level, chronic inflammatory state may induce insulin resistance and endothelial dysfunction and thus link the latter phenomena with obesity and cardiovascular disease." Additionally, data from the Hoorn study (Jager, A, van Hinsbergh, VW.M., Kostense, PJ., Emeis, JJ., Yudkin, JS., Nijpels, G, Dekker, JM., Heine, RJ., Bouter, LM., Stehouwer, CDA., von Willebrand Factor, C-Reactive Protein, and 5-Year Mortality in Diabetic and Nondiabetic Subjects : The Hoorn Study *Arteriosclerosis, Thrombosis, and Vascular Biology* (1999) **19**: 3071-3078) show that not only does CRP, but also increased levels of von Willebrand's factor "are independently associated with cardiovascular and all-cause mortality in both diabetic and nondiabetic subjects….Mutual adjustment of vWf and CRP did not markedly change the results, favoring the hypothesis that vWf and CRP predict mortality through different pathways."

3b) If so, can *conditions* which may precede diabetes but are not associated with poor control also be shown to associate with increased cardiovascular mortality?

Congestive Heart Failure Predicts the Development of Non-Insulin-Dependent Diabetes Mellitus in the Elderly[3b,4]

The Osservatorio Geriatrico Regione Campania Group. Amato L, Paolisso G, Cacciatore F, Ferrara N, Ferrara P, Canonico S, Varricchio M, Rengo F *Diabetes Metab* [1997] **23**:213-8

Congestive heart failure (CHF) is an insulin-resistant state which constitutes the main risk factor for the development of non-insulin-dependent diabetes mellitus (NIDDM). Our study investigated the predictive role of CHF on the development of NIDDM in 1,339 elderly subjects with a mean (+/- SD) age of 74.2 +/- 6.4 years. CHF had a 9.5% prevalence, and 14.7% of the subjects had NIDDM. After stratification by age, subjects between 80 and 84 years had the highest prevalence of CHF and a total of 29.6% of CHF patients had NIDDM. In multiple logistic regression analysis, CHF was associated with NIDDM [odds ration (OR) = 2.0, 95% confidence interval (CI) - 1.6-2.5] independent of age, sex, family history of diabetes, body mass index, (BMI), waist/hip ratio, and diastolic blood pressure. When only untreated CHF patients were taken into account, the association between CHF and NIDDM was even stronger (OR = 4.0, 95% CI = 3.4-5.8). When untreated CHF patients were grouped into those with low (I and II) and high (III and IV) New York Heart Association (NYHA) classes, the association of CHF and NIDDM was stronger with the worsening of CHF. In a longitudinal study, CHF predicted NIDDM independently of age, sex, family history of diabetes, BMI, waist/hip ratio, systolic and diastolic blood pressure, and therapy for CHF (OR = 1.4, 95% CI = 1.1-1.8). CHF was associated with a higher prevalence of NIDDM and was a risk factor for its development. Elevated FFA concentrations may play a pivotal role.

4) If so, can the *new onset* of diabetes be shown to associate with increased cardiovascular mortality?

SFU Warning

WARNINGS

SPECIAL WARNING ON INCREASED RISK OF CARDIOVASCULAR MORTALITY: The administration of oral hypoglycemic drugs has been reported to be associated with increased cardiovascular mortality as compared to treatment with diet alone or diet plus insulin. This warning is based on the study conducted by the University Group Diabetes Program (UGDP), a long-term prospective clinical trial designed to evaluate the effectiveness of glucose-lowering drugs in preventing or delaying vascular complications in patients with non-insulin-dependent diabetes. The study involved 823 patients who were randomly assigned to one of four treatment groups (DIABETES, 19, SUPP. 2: 747-830, 1970).

UGDP reported that patients treated for 5 to 8 years with diet plus a fixed dose of tolbutamide (1.5 grams per day) had a rate of cardiovascular mortality approximately 2½ times that of patients treated with diet alone. A significant increase in total mortality was not observed, but the use of tolbutamide was discontinued based on the increase in cardiovascular mortality, thus limiting the opportunity for the study to show an increase in overall mortality. Despite controversy regarding the interpretation of these results, the findings of the UGDP study provide an adequate basis for this warning. The patient should be informed of the potential risks and advantages of glipizide and of alternative modes of therapy.

Although only one drug in the sulfonylurea class (tolbutamide) was included in this study, it is prudent from a safety standpoint to consider that this warning may also apply to other oral hypoglycemic drugs in this class, in view of their close similarities in mode of action and chemical structure.

As with any other non-deformable material, caution should be used when administering GLUCOTROL XL Extended Release Tablets in patients with preexisting severe gastrointestinal narrowing (pathologic or iatrogenic). There have been rare reports of obstructive symptoms in patients with known strictures in association with the ingestion of another drug in this non-deformable sustained release formulation.

PRECAUTIONS

General

Renal and Hepatic Disease: The pharmacokinetics and/or pharmacodynamics of glipizide may be affected in patients with impaired renal or hepatic function. If hypoglycemia should occur in such patients, it may be prolonged and appropriate management should be instituted.

GI Disease: Markedly reduced GI retention times of the GLUCOTROL XL Extended Release Tablets may influence the pharmacokinetic profile and hence the clinical efficacy of the drug.

Hypoglycemia: All sulfonylurea drugs are capable of producing severe hypoglycemia. Proper patient selection, dosage, and instructions are important to avoid hypoglycemic episodes. Renal or hepatic insufficiency may affect

Strategies

Rx for Diabetes - Strategies

- Intensively treat hypertension (132/80)
- Minimize LDL-cholesterol (<100 mg/dl)
- Decrease postprandial proinsulinemia
- Decrease postprandial triglyceridemia
- Decrease SUR-2/mito k-ATP binding
- Increase fibrinolytic potential
- Decrease inflammation
- Maximize beta-cell survival
- Keep HbA1c < 8%

pharmanet
